Project 6 · Move a Windows Server from AWS to Azure

Where each piece lives, what Terraform builds, and what the Azure portal builds. Drawn from the files and the deployed state in 06-aws-to-azure-migrate-poc on Oct 26.

Where this stands (Oct 26)
Built and running in both clouds: the AWS network, the source server, the Azure network, the firewall attached to its subnet, and the discovery VM. The source firewall allows 445, 135 and 5985 from the subnet, and 5985 from the discovery VM's IP only. Both Azure groups carry lifetime=1d.
Still open
The replication appliance waits for the vCPU quota to reach 10. The Azure Migrate project and the portal steps are not done. AWS has no nightly delete, so tear it down by hand the same day as Azure.

Built with Terraform · Made in the portal or at cutover · Declared, not created yet
