Project 6 · Move a Windows Server from AWS to Azure

azure-aws-migrate-poc · redrawn Nov 2, 2026 from the Terraform files and the record · discovery, replication, test, cutover, complete; torn down Nov 2

made by Terraform · made in the portal or by hand · declared or planned, not created yet · Azure resource · outside Azure

Discovery, replication, a test migration, cutover, and complete all ran. The Azure appliance read the source over WinRM, then the AWS appliance copied the disk until Azure Migrate showed Protected and Healthy on Nov 1. Complete migration succeeded on Nov 2; the replicated item is gone.
The test copy booted in vnet-migrate-zeon and was cleaned up. Cutover left src-zeon running in rg-migrate-tgt-zeon01 on Nov 1. Teardown on Nov 2 removed the three Azure groups and the AWS network.
Azure Site Recovery counts Windows cores, not vCPUs: c5.2xlarge and the Azure appliance sizes showed 4 cores and failed; c5.4xlarge showed 8 and passed. vm-repl (variant B) failed the same check and was torn down with its group.
A solid box is built with Terraform, a dashed box is made in the portal or at cutover, and a dotted box is declared or planned and does not exist yet. GiB means gibibyte.
