# Project 6 · Move a Windows Server from AWS to Azure

azure-aws-migrate-poc · drawn Nov 1, 2026 from the Terraform files and the live build · discovery, replication, test migration and cutover done; teardown not run

made by Terraform · made in the portal or by hand · declared or planned, not created yet · Azure resource · outside Azure

Discovery, replication, a test migration, and cutover all ran. The Azure appliance read the source over WinRM, then the AWS appliance copied the disk until Azure Migrate showed Protected and Healthy. After cutover the portal item waits in a commit-pending state. The test copy booted in vnet-migrate-zeon and was cleaned up. The cutover left src-zeon running in rg-migrate-tgt-zeon01 on Nov 1. Teardown has not run.

Azure Site Recovery counts Windows cores, not vCPUs: c5.2xlarge and the Azure appliance sizes showed 4 cores and failed; c5.4xlarge showed 8 and passed. vm-repl (variant B) stays deallocated.

A solid box is built with Terraform, a dashed box is made in the portal or at cutover, and a dotted box is declared or planned and does not exist yet. GiB means gibibyte.
