Project 6 · Move a Windows Server from AWS to Azure

azure-aws-migrate-poc · drawn Oct 30, 2026 from the Terraform files and the live build · discovery done, replication not completed

made by Terraform · made in the portal or by hand · declared or planned, not created yet · Azure resource · outside Azure

Discovery is done: the Azure appliance read the source over Windows Remote Management (WinRM), and the Azure Migrate inventory listed src-zeon. That appliance was then deleted to free capacity.
Replication and cutover were not completed. The AWS replication appliance is declared but switched off: the account limit is 8 virtual CPUs (vCPUs), and the source plus the appliance need 10.
A request for 16 is open. Variant B puts the appliance (vm-repl) in Azure as a comparison. It is running, but whether it can copy from AWS is unverified, so that arrow stays dotted.
A solid box is built with Terraform, a dashed box is made in the portal or at cutover, and a dotted box is declared or planned and does not exist yet. GiB means gibibyte.
